```

Cross validation is one of the most popular methods for estimating test error and selecting tuning parameters, however, one can easily be mislead/confused by it without realizing it.

#### The Wrong Way

A model takes the dataset and finds that there are moderate correlations between some xs and y, and that the top 5 variables are not correlated. In this model noise can be fitted as well resulting in higher value in error e.

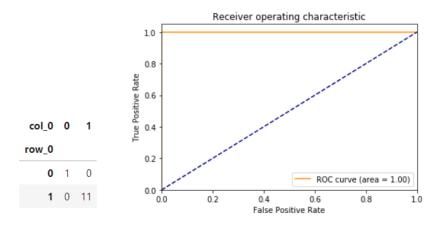

### The Right Way

The right way to do cross validation is to include the feature screening process in the cross validation as well.

Hence we have used feature to do the cross validation in this assignment.

### 1.d.iv)

the confusion matrix with AUC and ROC curve

1.d.v) Same as above is done for the test set, splitting the data and finding out the best L value which is 2

```

1.f.iii) Naive Bayes' classifier using Gaussian is better for multi-class classification in this problem

3.7.4) I collect a set of data (n = 100 observations) containing a single predictor and a quantitative response. I then fit a linear regression model to the data, as well as a separate cubic regression, i.e. Y = 60 + 61X + 62X2 + 63X3 + e.

a) Suppose that the true relationship between X and Y is linear, i.e. Y = 80 + 61X + e. Consider the training residual sum of squares (RSS) for the linear regression, and also the training RSS for the cubic regression. Would we expect one to be lower than the other, would we expect them to be the same, or is there not enough information to tell? Justify your answer.

Ans: It is expected the polynomial regression to have a lower training RSS than the linear regression because it could make a tighter fit against data that matched with a wider irreducible error e.

b) Answer (a) using test rather than training RSS.

Ans: It is the opposite of the answer for a), It is expected the polynomial regression to have a higher test RSS than the linear regression as the training would be overfitted and will increase the error e.

c) Suppose that the true relationship between X and Y is not linear, but we don't know how far it is from linear. Consider the training RSS for the linear regression, and also the training RSS for the cubic regression. Would we expect one to be lower than the other, would we expect them to be the same, or is there not enough information to tell? Justify your answer.

Ans: Because of higher flexibility, Polynomial regression has lower train RSS than the linear fit :no matter what the underlying true relationship is, the more flexible model will closer follow points and reduce train RSS.

d) Answer (c) using test rather than training RSS.

Ans: There is not enough evidence from the information provided to tell which test RSS would be lower for either regression given the problem statement is defined as not knowing how far it really is from linear. If it is closer to linear than cubic, the linear regression test RSS could be lower than the cubic regression test RSS. If it is closer to cubic than linear, the cubic regression test RSS could be lower than the linear regression test RSS. It is due to bias-variance tradeoff: it is not clear what level of flexibility will fit data better.

4.7.3) This problem relates to the QDA model, in which the observations within each class are drawn from a normal distribution with a class specific mean vector and a class specific covariance matrix. We consider the simple case where p = 1; i.e. there is only one feature.

Suppose that we have K classes, and that if an observation belongs to the kth class then X comes from a one-dimensional normal distribution,  $X \sim N(\mu k, \sigma 2 \ k)$ . Recall that the density function for the one-dimensional normal distribution is given in (4.11). Prove that in this case, the Bayes' classifier is not linear. Argue that it is in fact quadratic.

Ans:

$\frac{1}{b}(x) = \frac{1}{b} \left( \frac{1}{b} \left( \frac{x - x^{2}}{b^{2}} \right) \right)$ $\frac{1}{b} \left( \frac{1}{b} \left( \frac{x - x^{2}}{b^{2}} \right) \right)$ $\frac{1}{b} \left( \frac{1}{b} \left( \frac{x - x^{2}}{b^{2}} \right) \right)$
$\frac{\log(\pi_{k}) + \log(1 + 1)}{\log(\pi_{k})^{2} + \log(2\pi_{k})^{2}}$
$\log \left( \frac{1}{2\pi \sigma_1} \left( \frac{1}{2\pi \sigma_2} \left( \frac{1}{2\pi \sigma_1} \left( \frac{1}{2\pi \sigma_2} \right) $
69 (9 (N)) 109 [ ] 1 (x-11) = (275) =
$\frac{\log \left( \prod_{k} \right) + \log \left( \frac{1}{2 \prod_{k} x_{k}} \right) + -1 \left( x_{k} - \mu_{k} \right)^{2}}{2 \sigma_{k}^{2}}$
$\delta(x) = \log(\pi_{\mu}) + \log(\frac{1}{2\pi\sigma_{\mu}}) + \frac{1}{2\sigma_{\mu}^{2}}$
d(x) is a quadratic function of x

4.7.7) Suppose that we wish to predict whether a given stock will issue a dividend this year ("Yes" or "No") based on X, last year's percent profit. We examine many companies and discover that the mean value of X for companies that issued a dividend was  $^{T}X = 10$ , while the mean for those that didn't was  $^{T}X = 0$ . In addition, the variance of X for these two sets of companies was  $^{\circ}O2 = 36$ . Finally, 80% of companies issued dividends. Assuming that X follows a normal distribution, predict the probability that a company will issue a dividend this year given that its percentage profit was X = 4 last year.
